

# CAP 5400 - DIGITAL IMAGE PROCESSING

## Fall 2017 - Assignment 1

The purpose of this homework is to introduce you to the basic image manipulation techniques and to experiment with image smoothing and binarization techniques.

Your program should be able to do the following:

### 1. General modification

- You are to add all new processing to the image manipulation program given in assignment 0 (basic thresholding with parameter **T** and scaling with parameter **S**)
- Alternatively, you can implement the above by yourself
- Modify supplied script/program to access parameter file containing list of images, specification of the function to perform on each image, and set of parameters for each image. [1 point]

### 2. Processing of Images

- Implement rectangular region of interest (ROI) selection by specifying pixel location (**X,Y**) of the left-top pixel of ROI and ROI size (**Sx,Sy**). ROI should only be allowed within the image. Do not allow overlapping ROIs. Each of the following operations should be performed in ROI and combined image generated. Allow for up to 3 ROI per image. [2 point]
- Modify basic thresholding function to operate only within specified ROI(s). Allow different threshold for each ROI. [1 point]
- Implement uniform smoothing filter operation using square odd window size **WS**. Program two implementations: (a) regular 2D smoothing, (b) separable 1D incremental implementation of. Note that filter should be applied within ROIs only. Allow different **WS** for each ROI. [2 points]
- Add "edge-preserving" uniform smoothing of "size" **WS** (first input parameter) to your choice of options of gray level image processing. Let threshold **TWS** be the second user defined input parameter. Note: this is first method discussed in class which uses simple threshold. [2 points]
- Add color binarization option to your image processing toolbox. Let threshold **TC** be user defined input parameter. For color images, consider **TC** be a distance from user defined color **C(CR,CB,CG)** in RGB space. Set all pixels within **TC** distance to "white" and the rest to "black". This function should operate within specified ROI with different parameters for each ROI. [2 points]

Write the report for this assignment

- All programming assignments are to be done independently (not in group) without copying from internet. Code will be submitted electronically.
- create a "readme" file specifying format of the parameter file, describe all parameters and all run options (include in written report)

- **give an example of the parameter file set to process with several images with varying functions and parameters.**
  - **describe all operations and your implementations**
  - **include input and output example images for each function implemented (use several gray level and color images and at least two different thresholds as appropriate, multiple ROIs, etc)**
  - **discuss results and performance (including execution speed of two implementations) of uniform smoothing operation**
  - **discuss results of edge preserving smoothing operation**
  - **discuss results of color binarization (include discussion on microscopy images)**
- 

### **How to submit**

- **Submit paper report in class on the due date**
  - **See TA help desk for instruction on program submission and testing.**
-
